ArchiveBox Exporter supports two different modes of operation:

- **Allowlist:** Won't archive pages by default; you need to specify domains or regexes to archive
- **Blocklist:** Will archive every page by default; you can specify domains to ignore

No matter which mode you choose, how you add domains or regexes stays the same.

To add domains to your allowlist/blocklist, open the extension from your browser's toolbar. From here, you can see or modify your list:

The screenshot shows the ArchiveBox extension interface. At the top, there is a checkbox labeled "Regex?" followed by a text input field containing "Domain to add". To the right of the input field are three buttons: "+", "-", and "Clear". Below the input field is a large text area containing two lines of text: "*.stackoverflow.com" and "blog.horner.tj".

Domains

You can add full domains (e.g. `example.com`) or domain wildcards (e.g. `*.example.com`) to the list.

Regexes

You can also add regexes to test full URLs against, for more flexibility. To add a regex, toggle the **Regex?** checkbox before you add the entry. For example, if you wanted to automatically archive all Wikipedia wiki pages (all pages under `https://en.wikipedia.org/wiki/`), you could add a regex like this:

```
https?:\\/\\/en\\.wikipedia\\.org\\/wiki\\/\\.+
```

Regexes are evaluated as case-insensitive (there may be an option to change this in the future, though!)
